1. General Experimental

**Materials.** Silica gel (40 µm; 230–400 mesh) was from SiliCycle. Reagents were obtained from commercial sources and used without further purification. Dichloromethane and tetrahydrofuran were dried over a column of alumina. Thin-layer chromatography (TLC) was performed on plates of EMD 250 µm silica 60-F254.

**Solvent removal.** The phrase “concentrated under reduced pressure” refers to the removal of solvents and other volatile materials using a rotary evaporator at water aspirator pressure (<20 torr) while maintaining a water bath below 40 °C. Residual solvent was removed from samples at high vacuum (<0.1 torr).

**NMR spectroscopy.** $^1$H and $^{13}$C NMR spectra for all compounds were acquired with Bruker spectrometers in the National Magnetic Resonance Facility at Madison operating at 400, 500, 600, or 750 MHz. Chemical shift data are reported in units of δ (ppm) relative to an internal standard (residual solvent or TMS).

**Mass spectrometry.** Electrospray ionization (ESI) mass spectrometry for small-molecule characterization was performed with a Micromass LCT at the Mass Spectrometry Facility in the Department of Chemistry at the University of Wisconsin–Madison. Matrix-assisted laser desorption-ionization–time-of-flight (MALDI–TOF) mass spectrometry for protein characterization was performed with a Voyager DE-Pro instrument at the Biophysics Instrumentation Facility at the University of Wisconsin–Madison.

3. Measurement of Reaction Rate Constants

Each diazo compound and BocGlyOH were dissolved separately in CD$_3$CN at a concentration of 50 mM. The solutions were combined in an NMR tube at an equimolar ratio, mixed, and then inserted immediately into an NMR spectrometer. A 16-scan $^1$H NMR spectrum was acquired every 10 min. Percent conversion was monitored by disappearance of starting material and appearance of product as determined by integration of multiple $^1$H NMR spectral peaks. No other products were apparent by $^1$H NMR spectroscopy. The value of the second-order rate constant was determined by linear regression analysis of a plot of $1/[$diazo$]$ versus time. All reactions were performed in triplicate.

5. Protein Labeling

9-Diazofluorene was prepared as described previously.\textsuperscript{2} Yields and spectra matched the published data. Ribonuclease A (0.010 g, 0.73 µmol) was dissolved in 1 mL of 10 mM MES–HCl buffer at pH 5.5. 9-Diazofluorene (0.007 g, 0.036 mmol) was dissolved in 5 mL of CH₃CN. A 100-µL aliquot of the diazo stock solution was added to a 100-µL aliquot of the RNase A stock solution. The resulting mixture was mixed by nutation for 4 h at 37 °C. Any remaining diazo compound was then quenched by addition of 10 µL of 17.4 M acetic acid. Acetonitrile was removed by concentration under reduced pressure, and the aqueous solution of labeled protein was analyzed by MALDI–TOF mass spectrometry (Figures S2 and 5).
