

Title: Single Molecule Dynamics Reveals the Role of Flexibility in Bio-molecular Recognition

Jin Wang, Dept. of Chem. SUNY-Stony Brook

Abstract: With combined single molecule study of flexible protein binding with an energy landscape inspired microscopic model, we found strong evidences of bio-molecular recognition is determined by flexibilities in addition to structures. The single-molecule study show conformational fluctuations of the protein complex that involves bound and loosely bound states, which can be quantitatively explained in our model as a result of cooperative binding. Theoretical predictions on the key residues are consistent with mutational experiments. The combined study provides a test ground for fundamental mechanisms and insights for future explorations on recognition with large conformational changes.
